Abstract

This project analyses revenue dynamics and customer churn in a logistics company to support data-driven decision-making and improve long-term performance. The company's vision is to achieve sustainable growth through efficient logistics operations and strong customer relationships, while its mission focuses on delivering reliable and scalable transport solutions. The main business challenge addressed is the decline in revenue driven by changes in customer activity. The objective of the analysis is to identify the drivers of this decline and define actionable strategies to improve customer retention and revenue stability.

The company's business needs include better visibility over customer behaviour, early detection of revenue deterioration, and more targeted commercial strategies. The analysis reveals a strong competitive advantage in data availability, enabling advanced analytics across customers, sectors, and geographic regions.

Results show that revenue is highly concentrated, with 20% of customers generating 93.8% of total revenue, and that churn is primarily driven by declining activity among existing clients. This creates both risk and opportunity. Key risks include dependency on high-value clients, sector exposure, and geographic concentration. However, opportunities exist in recovering at-risk customers, optimizing sector strategies, and improving regional targeting.

The proposed strategy focuses on implementing an early-warning system, prioritizing high-value customer recovery, and adopting differentiated actions across sectors and regions. While the company demonstrates a solid operational and technological foundation, further investment in data quality and analytics capabilities is recommended to support scalable growth and competitive advantage.

Keywords and Expressions

Revenue Concentration, Predictive Analysis, Behavioural Segmentation, Data-Driven Decision Making, Churn Analysis

1 Introduction

The role of the logistics sector in modern supply chains is critical, as it facilitates the movement of goods in an efficient manner in an increasingly complex and dispersed market (Christopher, 2016). As competition in the market is rising and the business environment is becoming more challenging in terms of reduced business margins, it is not only essential to make improvements in the business processes but also to develop a deeper understanding of the clients and their demands.

With the rise of transactional data, there is an opportunity to make data-driven decisions (Waller and Fawcett, 2013). However, there is still a lack of structural analytical frame work that enables businesses to comprehend client behaviour and make decisions in advance to maintain the business's stability and growth in the long term. Especially, comprehending the revenue generated from clients and its evolution over time is essential in maintaining business stability and growth.

To address these challenges, this study aims to analyse revenue data of the clients of the logistics firm and understand their behaviour over time. The clients are observed over a period of 36 months, allowing to analyse their behaviour over time.

In contrast to traditional methods that view customer churn as a yes or no event, this study takes a behavioural and revenue-based view (Neslin et al., 2006). It does not just focus on customer inactivity; it also looks at gradual declines in activity as early signs of disengagement. This difference is very important in business-to-business (B2B) logistics, where clients often decrease shipment volumes slowly instead of ending the professional relationship suddenly. Additionally, the analysis includes forward-looking indicators from predictive models (Verbeke et al., 2012). By blending historical performance and transactions with short-term forecasts, this project helps identify early warning signals of revenue decline, which allows for timely intervention.

2 Literature Review

2.1 Logistics and Data-Driven Decision Making

The role of logistics has transformed from an operational to a strategic function in supply chain management. This is because of the increasing complexity of the network and the variability of demand, which necessitate timely and informed decisions (Christopher, 2016). Thus, data analytics is an essential tool in enhancing the visibility, performance and responsiveness of the logistics function (Waller and Fawcett, 2013):

This can be attributed to the increasing adoption of data-driven decisions, which encompass various forms of descriptive, diagnostic, predictive, and prescriptive analytics to support

strategic decisions (Davenport and Harris, 2007). These types of decisions are essential in the logistics function because of the large-scale operations and demand variability.

2.2 Revenue Concentration and Business Risk

Revenue concentration is another common phenomenon in a business in which the majority of the revenue is generated by a small percentage of customers. This phenomenon is closely linked with the Pareto principle (Koch, 2008). However, this structure also poses risks because the business is now heavily dependent on a small number of clients.

The risks posed by this structure can be quantified with the help of the Gini coefficient and the Lorenz curve, which quantify the inequality in value distribution (Cowell, 2011). In customer portfolio management, high concentration levels imply that a decrease in revenue is likely to be driven by a small number of economically significant customers.

As shipment volumes are often dominated by a limited number of large accounts, understanding concentration is therefore essential for evaluating structural risk.

2.3 Customer Churn

Typically, customer churn is defined as the termination of a contractual relationship, with particular emphasis on subscription-based businesses (Neslin et al., 2006). However, in B2B environments, churn is more gradual.

Recent research distinguishes between hard churn and soft churn, where declining engagement precedes full customer loss (Verbeke et al., 2012). This approach is better suited in continuous service environments, where customers may reduce activity rather than stop suddenly.

2.4 Revenue-Based Churn and Early Warning Systems

As customer value is not evenly distributed, revenue-based churn analysis is more relevant than customer-based churn analysis (Fader and Hardie, 2009). This is because the loss of a few high value customers in the case of a high concentration portfolio would affect the overall revenue generated.

Early warning systems are designed to address this problem through the early detection of declining customer activity using behavioural indicators (Verbeke et al., 2012). This is very useful in the logistics sector because the volume of shipments is likely to be indicative of the customer’s demand patterns.

2.5 Customer Segmentation and Portfolio Analysis

Customer segmentation is the process of grouping customers according to their characteristics and behaviours (Wedel and Kamakura, 2000). This is very useful in developing appropriate marketing strategies.

Portfolio analysis is another useful concept that helps firms segment their customers using the BCG matrix (Henderson, 1970). This matrix is useful in developing appropriate marketing strategies according to the performance of the customer segments. This is very useful in allocating resources effectively, especially in the case of heterogeneous B2B markets.

2.6 Temporal Analysis and Seasonality

Time series analysis presents a framework to grasp temporal patterns, such as trends, seasonality and volatility (Hyndman and Athanasopoulos, 2021). In logistics, seasonality is relevant due to cyclical demand in sectors, such as retail and manufacturing.

Failure to grasp these trends may cause an organisation to misinterpret customer behaviour. A dip in activity may be perceived as an indication of declining customer base. Therefore, temporal analysis is critical in distinguish between these trends.

2.7 Prescriptive Analytics and Decision Support

Machine learning and prescriptive analytics have been used in business settings due to their ability to analyse data with intricate relationships (James et al., 2021). In churn prediction, methods like ensemble models have shown promising results (Verbeke et al., 2012).

However, it is critical to strike a balance between predictive accuracy and interpretability. Comprehending the drivers of predictions is essential for translating analytical outputs into actionable decisions.

2.8 Research Gap and Contribution

While the existing literature has covered the concepts of revenue concentration, churn analysis, demand forecasting and segmentation separately, the reality is that these are interconnected. The contribution of the study is the integration of these concepts of revenue structure, churn diagnostics, segmentation and demand forecasting.

This integration of customer behaviour with sectoral and geographical dynamics is more effecting in comprehending the dynamics of revenue decline in the logistics sector.

3 Data and Methodology

3.1 Research Design and Analytical Framework

This research uses a data-driven analytical framework to analyse the revenue structure, customer churn, and support strategic decision-making. This framework progresses through descriptive analytics, diagnostic analytics, behavioural segmentation, and finally prescriptive analytics. This progression is in line with existing frameworks of business analytics (Davenport & Harris, 2007).

The analytical process is divided into four stages: descriptive analytics (revenue structure and composition of the portfolio), diagnostic analytics (causes of customer churn and revenue decline), behavioural segmentation (segmenting customers based on their behaviour), and prescriptive analytics (actionable insights for strategic business decisions). These analytics were applied to customers, industries, geographical areas, and interactions among them, enabling the identification of localized performance patterns and targeted interventions.

3.2 Data Description and Preprocessing

The data set contains client-level data with reported revenue for 36 monthly variables (M-35 to M-0).

Data Preparation involves aggregating monthly revenue into total customer revenue, structuring two six-month periods for assessing recent performance, addressing missing categorical data by adding an “Unknown” category, and ranking clients by revenue contribution for prioritization purposes.

This process is consistent with establishing suitability for both statistical and business interpretation.

3.3 Descriptive Analytics: Revenue Structure Analysis

Revenue concentration was assessed using complementary techniques:

- Pareto analysis to identify key revenue-generating customers (Koch, 2008)
- Gini coefficient to quantify inequality (Cowell, 2011)
- Lorenz curve to visualize revenue distribution (Cowell, 2011)

A churn sensitivity analysis was conducted by simulating the impact of reduced activity among top customer segments to evaluate business fragility.

Sector analysis was carried out using ATECO classification, entailing revenue aggregation, client counts and average revenue per client. Results were visualized using multi-dimensional scatter plots.

A BCG matrix framework (Henderson, 1970) was implemented to classify sectors based on growth and revenue contribution to support strategic portfolio interpretation.

3.4 Diagnostic Analytics: Churn and Revenue Decline

Customers were grouped into three activity states: active (stable or increasing activity), fading (declining activity) and inactive (no recent activity).

Churn was tracked on a revenue-weighted basis to reflect economic impact. This analysis was conducted across geographic (macro-regions and territories) and sector (ATECO) dimensions in order to pinpoint areas where revenue loss is occurring.

Time-series analysis of monthly revenue was used to assess seasonality, volatility, and demand fluctuations, enabling differentiation between temporary variation and structural decline.

3.5 Behavioural Segmentation

A behavioural segmentation approach (Wedel & Kamakura, 2000) was implemented by incorporating activity states, revenue contribution and sector/geographic attributes.

This allowed the identification of high-value at-risk customers, stable segments and sector-specific behavioural patterns.

3.6 Prescriptive Analytics

The analytical insights were then translated into actionable strategies, consistent with data-driven decision-making principles (Davenport & Harris, 2007).

Forecast data was incorporated to evaluate expected performance and identify continued decline trends and a multi-level decision framework was developed by integrating customer-level prioritisation with sector-level strategies and geographic targeting, enabling the transition from analysis to actionable business decisions.

3.7 Visualization and Analytical Tools

Data analysis and visualization were conducted using Python. Key tools, such as Pandas and NumPy supported data aggregation, statistical analysis, and visualization of revenue patterns. Advanced visualization techniques, like multi-dimensional charts and time-series smoothing, were used to support interpretation and communication of results.

3.8 Evaluation Strategy

The analytical framework is evaluated based on its ability to: identify high-risk, high-value segments, quantify revenue exposure and decline and support targeted and actionable decision-making.

The focus is on ensuring practical business relevance and direct applicability to managerial decisions.

4 Results and Discussion

4.1 Revenue Structure and Portfolio Composition

4.1.1 Revenue Concentration

The analysis of revenue concentration shows that there is a highly unequal distribution across the client base. Pareto analysis confirms that a small proportion of clients generates the majority of revenue, with the top 20% accounting for 93.8% of total company revenue (Figure 1).

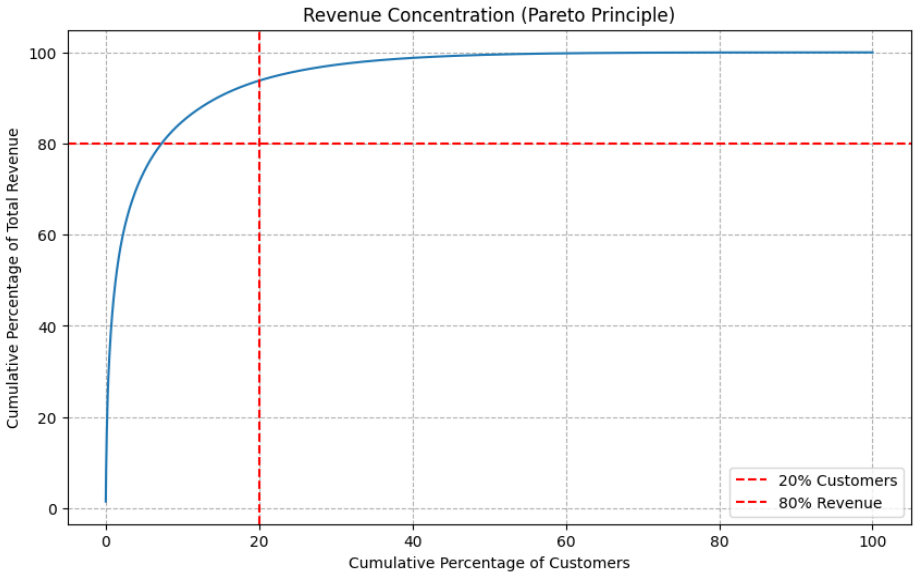

Figure 1 – Revenue Concentration (Pareto Principle)

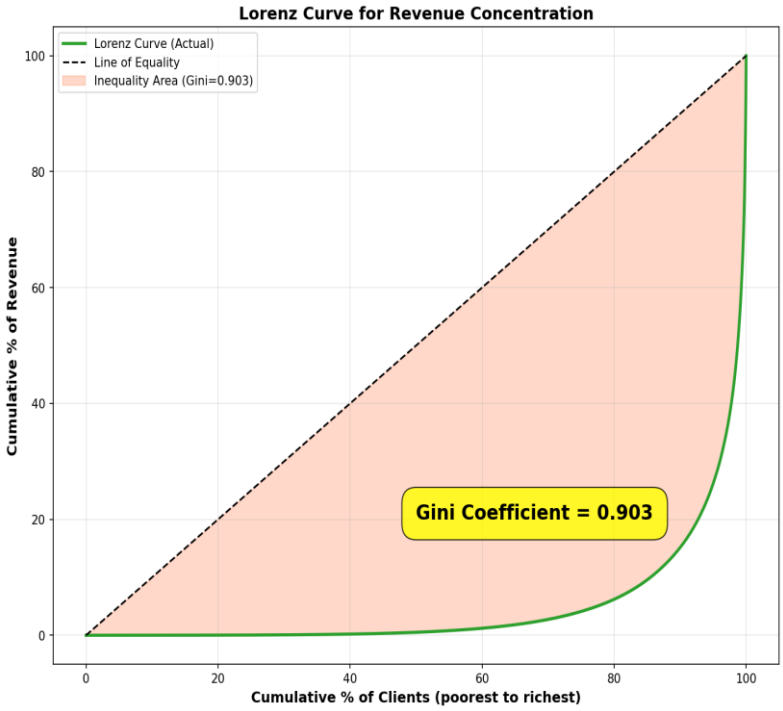

Figure 2 – Lorenz Curve and Gini Coefficient

This finding is reinforced by inequality measures. The Gini coefficient is 0.903, indicating extreme concentration and exceeding typical industry benchmarks (0.5–0.7 for logistics and B2B services). The Lorenz curve further illustrates this imbalance (

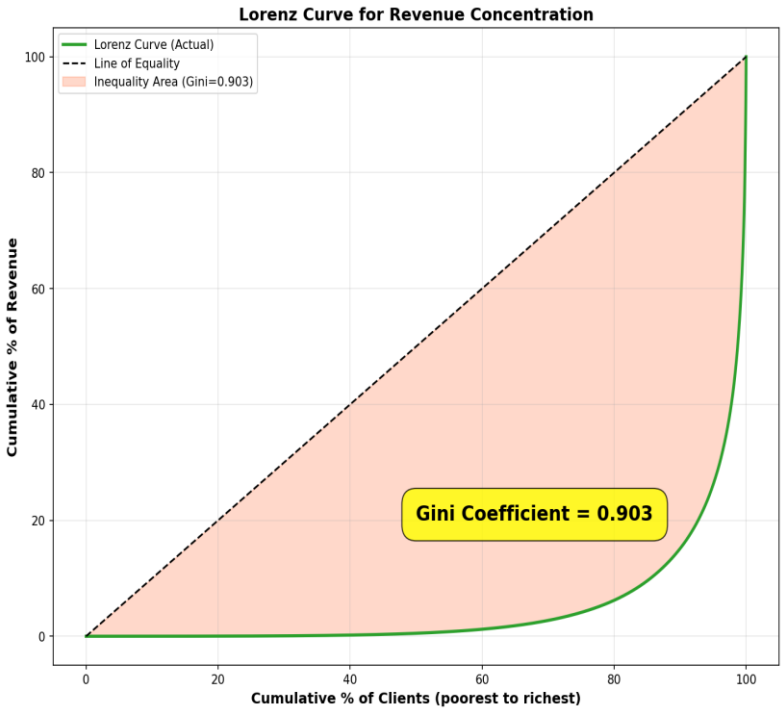

Figure 2).

This level of concentration implies a strong dependency on a limited number of high-value clients, exposing the company to significant concentration risk. Small variations in the behaviour of these key accounts can generate disproportionately large changes in total revenue. This structural fragility provides a critical foundation for the subsequent analysis,

suggesting that revenue decline is likely to be driven by changes in a relatively small number of economically significant customers.

4.1.2 Revenue Sensibility and Risk Exposure

To assess business fragility, a churn sensitivity analysis was conducted, simulating the impact of losing top-performing client segments.

The results highlight the extreme sensitivity of the company's revenue to its largest accounts. The loss of just 5% of top clients would result in a reduction of approximately € 249.5 million, equivalent to 73.84% of total revenue. Expanding this scenario, the loss of the top 10% of clients would eliminate nearly 85% of total revenue.

These findings confirm that revenue concentration is not only a structural characteristic but also a critical risk factor. The company's performance is highly dependent on a small number of high-value clients, making it particularly vulnerable to changes in their activity.

This reinforces the importance of early detection of customer decline, especially among top-tier accounts, as even small variations can have a disproportionate financial impact.

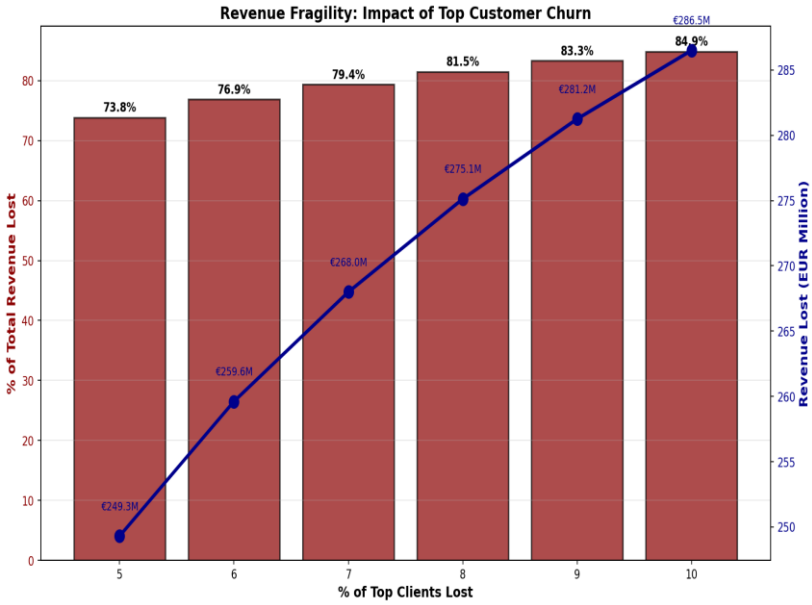

Figure 3 – Revenue Fragility Analysis

4.1.3 Sector Performance and Portfolio Structure

Sectoral analysis based on ATECO classification reveals that revenue is unevenly distributed across industries, with a limited number of sectors accounting for a large share of total revenue. Wholesale and retail trade dominates the portfolio, contributing approximately 41% of total revenue and representing the largest share of clients. Transportation and storage also contribute significantly, combining high revenue with a more moderate client base (Figure 4).

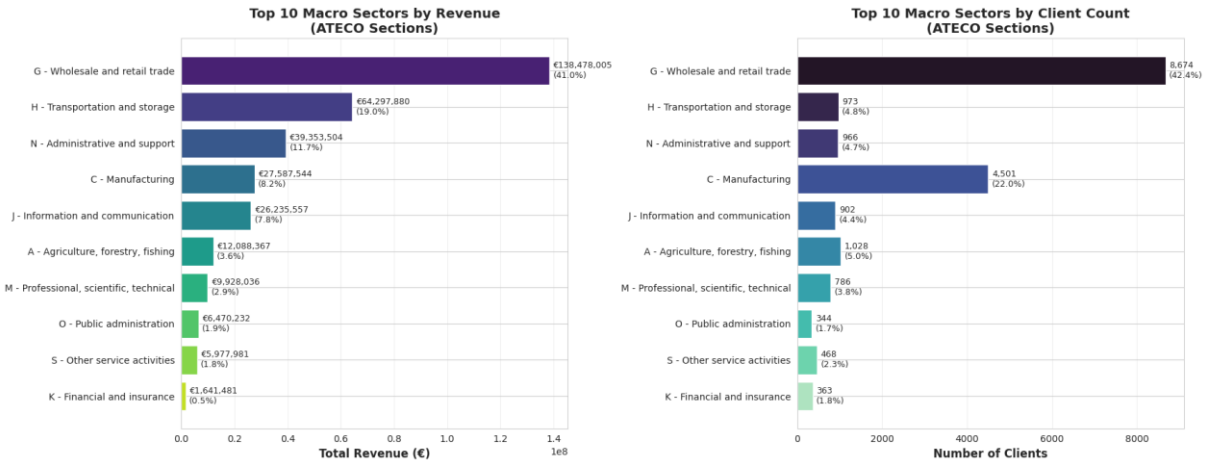

Figure 4 – Top 10 Macro Sectors by Revenue (left) and by Client Count (right)

At a more detailed level, sector performance varies considerably. E-commerce retail generates the highest total revenue but exhibits relatively low revenue per client, indicating a high-volume, lower-margin profile. In contrast, logistics services and office support demonstrate higher revenue per client (approximately €185K and €105K respectively), reflecting stronger pricing or higher-value contracts. These sectors are explained in more detail on Table 7

These discrepancies are visible in the sector portfolio matrix (Figure 6), where logistics services occupy a premium position (combining relatively high revenue with lower client volume). E-commerce is the opposite, with a high volume but lower per-client value. Office support achieves the highest pricing levels despite lower overall scale.

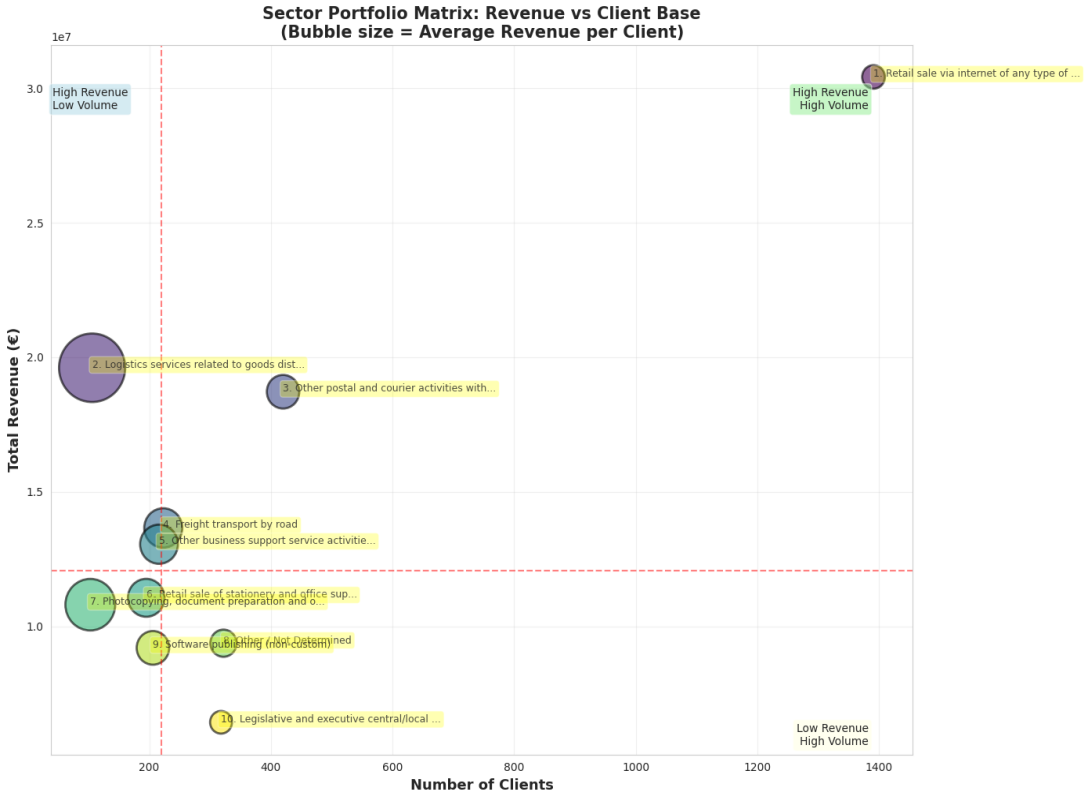

Figure 5 – Sector Portfolio Matrix

The results indicate that the company's revenue base is highly dependent on a limited number of key sectors. While this concentration supports scale, it also introduces sectoral risk, as changes in demand or competitive conditions within these sectors can have a disproportionate impact on performance.

This provides an important foundation for subsequent analyses, as sector-level dynamics are likely to influence patterns of churn and customer behaviour.

4.1.4 Growth Dynamics and BCG Matrix

The sector portfolio was further analysed using a BCG matrix framework, classifying sectors into Stars, Cash Cows, Question Marks, and Dogs based on growth and revenue contribution.

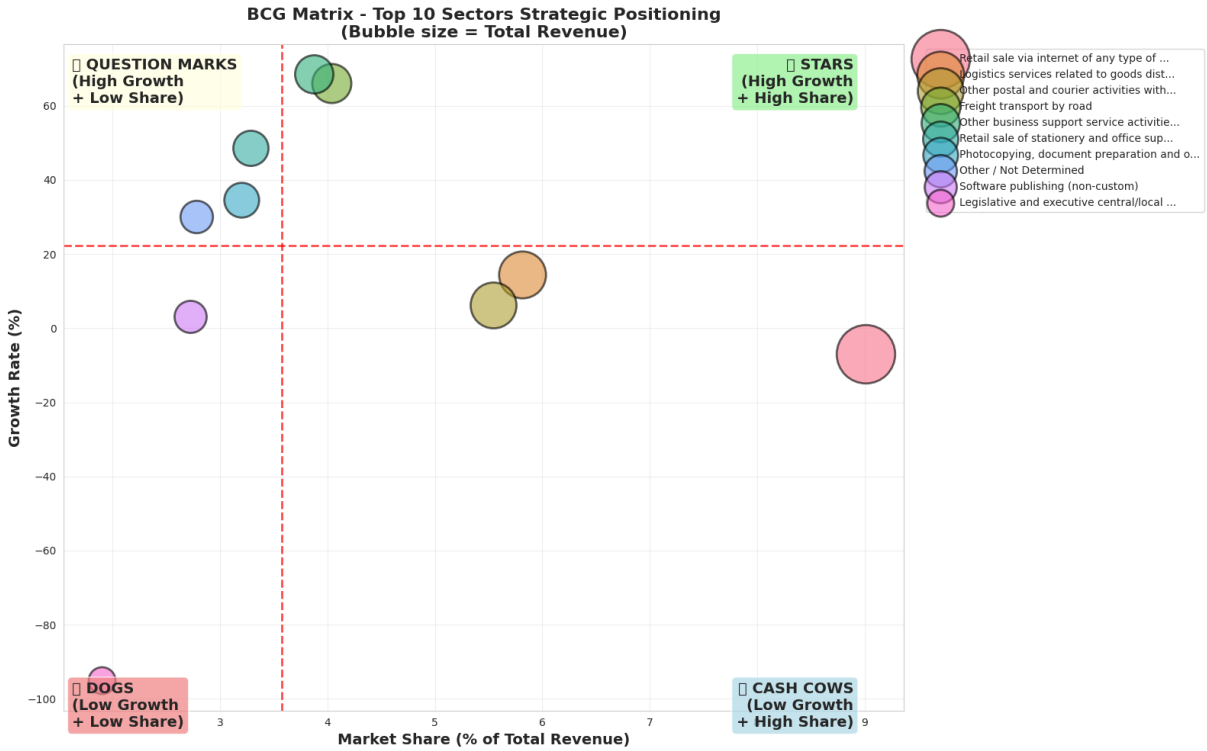

Figure 6 – BCG Matrix of Top 10 Sectors

The results highlight clear differences in sector positioning. High-growth, high-revenue sectors represent the company's primary growth engines and require continued investment. In contrast, high-revenue but low-growth sectors provide stable income streams and should be managed through defensive strategies.

Sectors with high growth but lower contribution represent potential opportunities, requiring selective investment to strengthen their position. Conversely, low-growth, low-contribution sectors contribute limited value and may require resource reallocation. A summary of the BCG Matrix is provided on Annex A.

Overall, the BCG analysis reinforces the importance of balancing short-term revenue stability with long-term growth, supporting more effective portfolio management and resource allocation decisions.

4.1.5 Geographic Distribution of Revenue

Revenue is unevenly distributed across geographic regions, highlighting a strong concentration in a limited number of key areas. At a detailed level, Milano is the largest territory, and together with Monza, Varese, and Brescia accounts for approximately 20% of total company revenue (Figure 7). These territories represent the core of the company's geographic footprint.

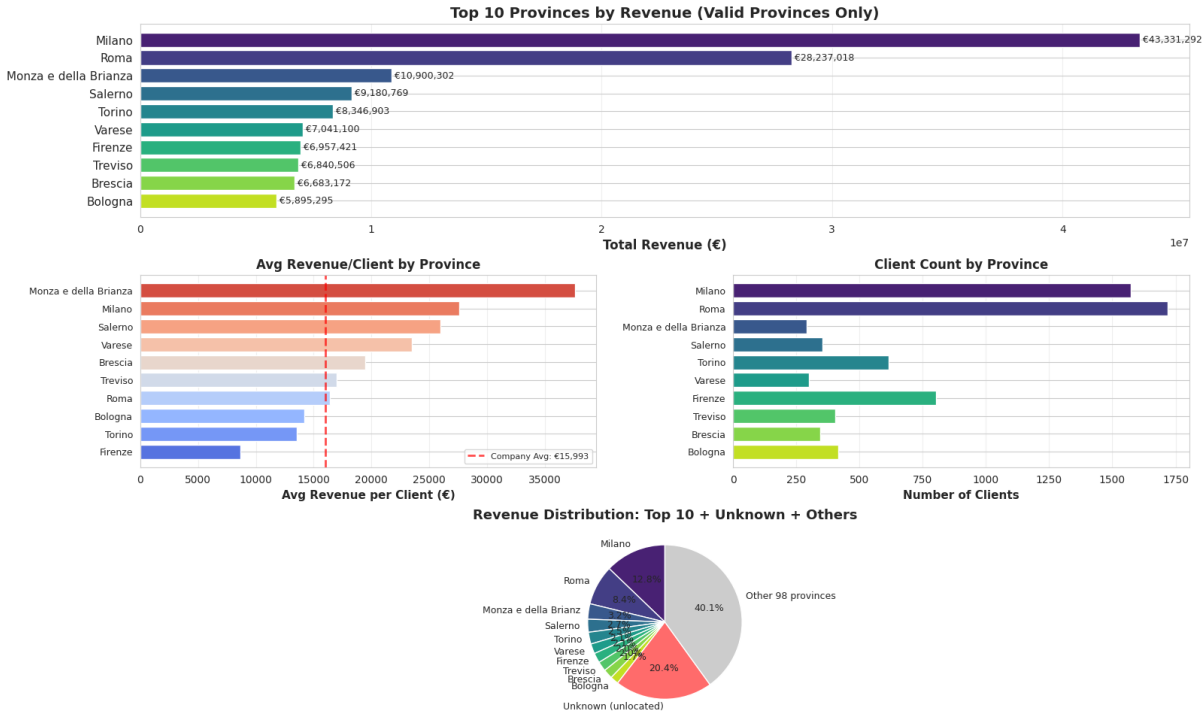

Figure 7 – Top Provinces

At a macro-regional level, the Northwest dominates the revenue base, generating approximately €107.7 million, equivalent to 31.9% of total revenue (Figure 8). The "Unknown" category represents a significant share at 20.1%, highlighting a limitation in geographic data quality

Client distribution further supports this pattern. While the Northwest and Centre host a similar number of clients, their revenue contributions differ significantly, indicating variation in average customer value. This suggests that regional performance is driven more by client quality than by client volume.

Overall, these results highlight two key structural insights. First, geographic concentration creates dependency on a limited number of regions, increasing exposure to localized risks. Second, differences in average revenue per client indicate that some regions offer higher-value

opportunities, while others may represent growth potential through improved targeting and pricing strategies.

From a strategic perspective, high-revenue regions such as the Northwest act as critical revenue anchors but also represent key sources of risk. At the same time, lower-performing regions may offer opportunities for expansion.

Finally, the large “Unknown” geographic category reduces the precision of the analysis and should be addressed as a data quality priority.

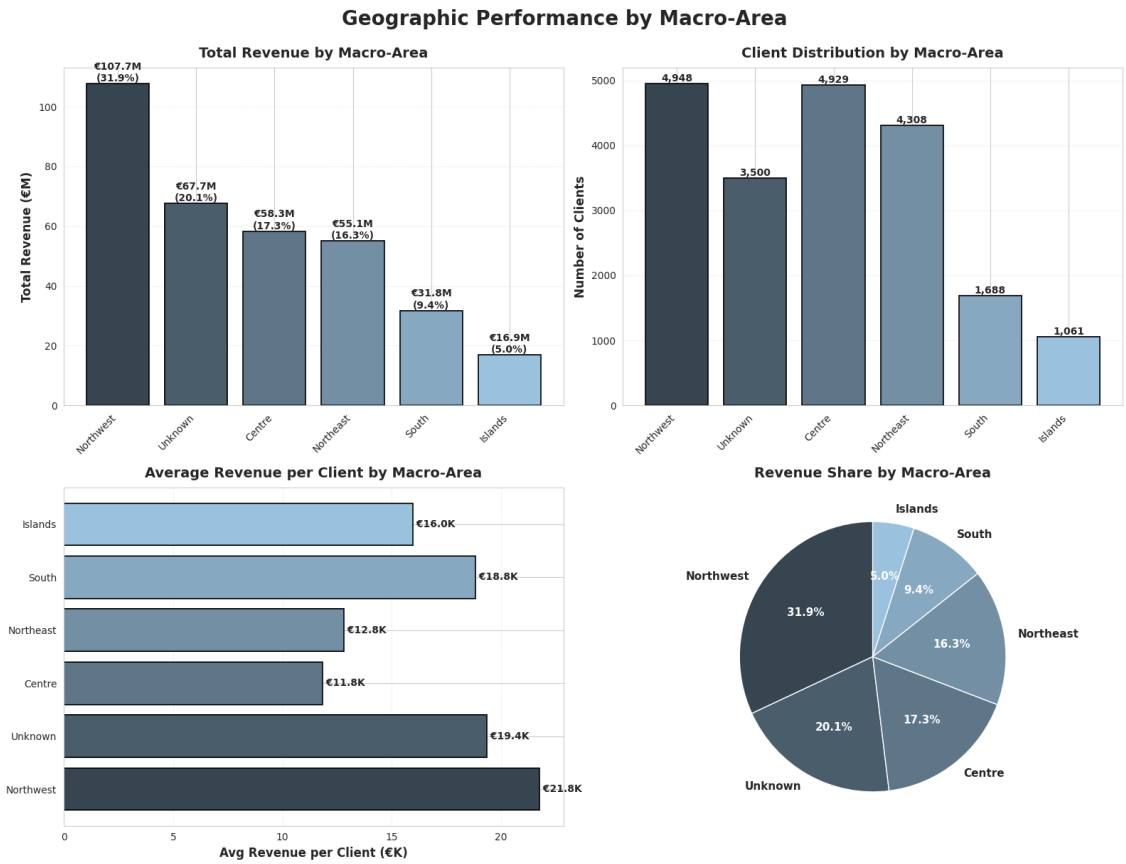

Figure 8 – Macro-Regions Performance

4.1.6 Strategic Implications for Revenue Structure

The results of Section 4.1 provide a critical foundation for interpreting customer churn dynamics and revenue risk. First, the extreme level of customer concentration indicates that revenue is driven by a small number of high-value accounts. The company shows strong dependency on approximately 1,000 “whale” clients, with the top 5% generating around 74% of total revenue.

Second, sector concentration suggests that industry-specific dynamics will play a key role in shaping performance. High-revenue sectors represent both strategic opportunities and surces of vulnerability.

Third, geographic concentration indicates that revenue risk is unevenly distributed, reflecting local market conditions and differences in customer value across regions. Overall, these findings confirm that revenue risk is highly concentrated and structurally predictable, rather than random. This provides a strong basis for the targeted analysis of churn and behavioural patterns developed in subsequent sections.

4.2 Customer Churn and Demand Dynamics

4.2.1 Company-Level Churn Diagnostic

As described in Table 1, the company is experiencing significant revenue pressure driven primarily by declining activity among existing customers rather than complete customer loss. Across €336.8 million of historical revenue, revenue-weighted churn reaches 37.7%, of which 28.9% is associated with at-risk (fading) customers and 8.8% with inactive customers.

Metric	Value
Historical revenue	336.76M€
Recent 6-month revenue	61.97 M€
Prior 6-month revenue	56.69 M€
Forecast next 6 months	48.73 M€
Revenue-weighted churn	37.7%
Inactive share	8.8%
At-risk share	28.9%
Lost revenue vs prior 6 months	9.61 M€
Forecast change vs recent 6 months	-21.4%

Table 1 – Company-Level KPIs

Recent performance shows € 61.97 million in revenue over the last six months, representing a 9.3% increase compared to the previous period. However, the forward-looking forecast indicates a decline to € 48.73 million over the next six months, corresponding to a projected decrease of 21.4%. This suggests that current performance is not sustainable and that underlying weaknesses persist

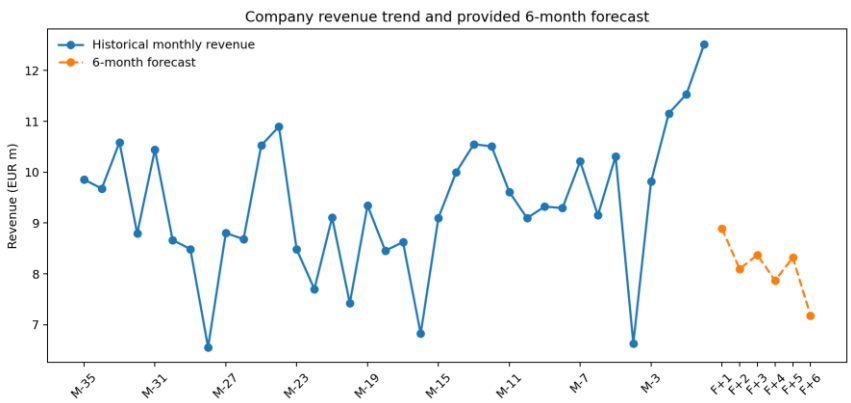

Figure 9 – Company Revenue Trend and 6-months forecast

The forecast in Figure 9 shows that the primary factor causing the revenue decline is the progressive deterioration of the customers' activity, rather than abrupt churn. This creates an opportunity for early intervention before customers become fully inactive.

4.2.2 Geographic Analysis – Macro-Regions

Customer churn varies significantly across macro-regions, indicating that revenue decline is not geographically uniform.

The Northwest represents the largest exposure, accounting for 31.9% of total revenue and € 3.01 million already lost. It combines high scale with elevated churn, making it one of the most critical risk areas. The Northeast and Centre exhibit the highest churn rates, at 43.8% and 40.7% respectively, indicating structurally weaker customer retention. In contrast, the Islands region shows lower churn (18.6%) and recent growth, suggesting a more resilient segment, while the South is the only region currently experiencing contraction (-4.8%).

Table 4 summarizes macro-region performance across revenue share, churn, recent momentum, and forecast. The key insight is that risk is concentrated where high revenue share overlaps with high churn and weak forward outlook, particularly in the Northwest, Centre, and Northeast.

Macro-region	Hist €M	Share %	Churn %	6m chg %	Lost (€M]	Fcst (€M)	Fcst %
Northwest	107.54	31.9	38.6	6.2	3.01	15.75	-16.8
Unknown	67.48	20.0	37.2	25.2	2.28	10.11	-34.0
Centre	58.17	17.3	40.7	3.3	1.45	7.55	-14.6
Northeast	54.97	16.3	43.8	6.5	1.40	7.74	-18.2
South	31.73	9.4	29.8	-4.8	1.18	5.22	-10.6
Islands	16.86	5.0	18.6	17.1	0.30	2.36	-34.0

Table 2 – Macro-Region Performance

This confirms that the company should not manage the market with a uniform national strategy, but instead adopt region-specific approaches reflecting local demand conditions, sector exposure, and competitive dynamics.

Figure 10 further illustrates this relationship by comparing revenue share and churn rates across macro-regions. While the Northwest is the largest contributor to revenue, the Northeast and Centre carry the highest churn intensity, reinforcing the concentration of risk. In contrast, smaller regions such as the Islands exhibit more stable performance.

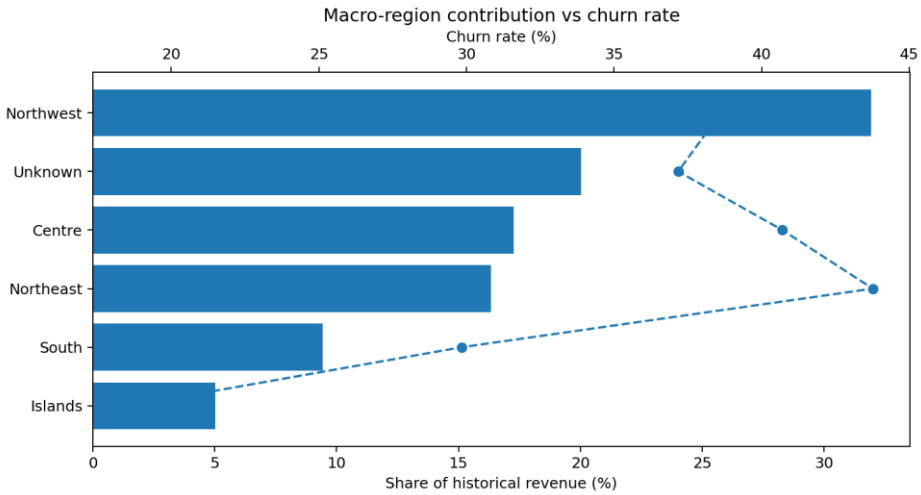

Figure 10 – Macro-region Contribution vs Churn Rate

Forecast analysis indicates that all macro-regions are expected to contract over the next six months, with the most significant decline projected in the Islands (-34.0%), followed by the Northeast (-18.2%), Centre (-14.6%), and South (-10.6%). This suggests that even regions with recent positive performance are unlikely to sustain growth, highlighting the need to move from reactive diagnosis to proactive intervention. This data is shown on Figure 17

Finally, a significant limitation is the presence of a large “Unknown” geographic category, representing 20% of total revenue, shown in Figure 18. This segment also exhibits a negative forecast and an inactive share of approximately 14%, reducing the reliability of regional analysis. Improving geographic data quality should therefore be treated as a priority.

4.2.3 Territory-Level Analysis

At a more granular level, territory-level analysis highlights that revenue decline is concentrated in a limited number of economically significant municipalities.

Milano is the largest territory, accounting for 12.86% of total revenue and representing the largest loss pocket (€ 1.12 million). Roma follows with 8.37% of revenue and € 0.75 million lost. These territories combine high revenue concentration with substantial decline, making them the most critical areas of risk. In contrast, smaller territories such as La Spezia and Benevento exhibit sharper contractions (-51.8% and -81.4%), but their overall impact is limited due to their smaller revenue base.

At the same time, certain territories demonstrate more resilient performance. Palermo shows low churn (6.5%) and strong recent growth (21.3%), while Varese combines relatively low churn (13.2%) with a slightly positive forecast (1.3%), indicating early signs of stabilization.

Table 5 presents the top municipalities by revenue contribution and performance indicators. The key insight is that large territories with declining performance represent the greatest economic risk, as even moderate deterioration translates into significant absolute revenue loss.

Territory	Hist (M€)	Share %	Churn %	6m chg %	Lost (M€)	Fcst (M€)	Fcst %
Milano	43.30	12.9	44.8	16.4	1.12	6.03	-23.9
Roma	28.19	8.4	31.5	-0.1	0.75	3.43	-16.7
Monza e della Brianza	10.89	3.2	36.4	-1.6	0.31	1.77	-16.3
Salerno	9.17	2.7	28.5	-5.5	0.24	1.55	0.1
Torino	8.33	2.5	43.1	3.0	0.22	1.16	-14.3
Varese	7.03	2.1	13.2	-8.8	0.23	1.24	1.3
Firenze	6.94	2.1	45.7	9.2	0.14	0.89	-16.0
Treviso	6.83	2.0	19.4	-7.6	0.28	1.05	-6.1
Brescia	6.67	2.0	50.8	17.5	0.10	0.97	-23.2
Bologna	5.88	1.7	50.1	4.9	0.09	0.77	-16.8

Table 3 – Top 10 Municipalities data

Additional insight is provided by the identification of problematic and recovering territories (Annex B: Figure and Tables (section 4.2)). Problematic territories are characterized by a combination of high revenue loss, elevated churn, and negative recent momentum. In several cases, these include economically relevant municipalities where deterioration is not marginal but structurally significant, reinforcing the need for targeted intervention at the local level.

Conversely, recovering territories exhibit a positive forecast following a period of decline. However, this recovery should be interpreted with caution, as it often reflects stabilization from a weakened base rather than a return to previous performance levels. Two distinct profiles emerge: larger territories with moderate decline and early signs of stabilization (e.g., Varese and Salerno), and smaller territories with severe contraction but positive forecast dynamics (e.g., Terni, Foggia, and Ancona). The former represents stronger candidates for proactive recovery initiatives due to their economic relevance, while the latter require careful monitoring, as their apparent growth is driven by low base effects.

4.2.4 Sector Analysis

Sectoral analysis reveals that revenue decline is concentrated in a limited number of industries, with risk driven by both sector size and performance dynamics.

Ateco G.47.91.10 represents the largest sector exposure (9.01% of total revenue) and the largest source of lost revenue (€ 1.13 million), making it a key driver of overall decline. Ateco H.53.20.00 emerges as the highest-risk large sector, combining elevated churn (51.4%) with a strongly negative forecast (-32.1%). Similarly, Ateco H.52.29.22 shows high churn (43.6%) alongside significant revenue contribution. In contrast, sectors such as G.47.62.20, J.62.02.00, O.84.11.10, and J.62.01.00 demonstrate greater resilience, with lower churn and/or more stable outlooks.

Table 4 ranks sectors by revenue contribution and summarizes their performance across churn, recent momentum, lost revenue, and forecast. The key insight is that large sectors with weak performance represent structural vulnerabilities, while large and stable sectors act as strategic anchors for the company.

AtecoCode	AtecoDesc	Hist (M€)	Share %	Churn %	6m chg %	Lost (M€)	Fcst (M€)	Fcst %
G.47.91.10	E-commerce retail	30.34	9.0	41.6	4.7	1.13	4.50	-17.1
H.52.29.22	Freight transport	19.61	5.8	43.6	18.0	0.40	2.92	-23.5

Table 4 – Top ATECO Codes by Revenue Contribution

Sector composition is therefore a critical determinant of overall performance. A portfolio heavily concentrated in fragile industries will remain unstable even if geographic performance improves. Different sectors are also subject to distinct demand patterns, including seasonality, economic cycles, and competitive dynamics, requiring differentiated management approaches. Further analysis of problematic and outperforming sectors, detailed in Table 11 and Table 12 reinforces this conclusion. Problematic sectors are those combining meaningful revenue exposure with high churn, declining momentum, and/or negative forecast. These include sectors where deterioration is already material, as well as those where forward outlook suggests continued decline. In contrast, outperforming sectors exhibit stronger retention and more stable demand patterns, making them suitable targets for expansion and replication of successful commercial practices.

The sector risk matrix (Figure 11) provides a visual summary of these dynamics by mapping churn against forecast performance. Sectors such as H.53.20.00, H.52.29.22, and G.47.91.10 are positioned in the high-risk quadrant, combining high churn with negative outlook and significant economic weight. Conversely, sectors such as G.47.62.20, J.62.02.00, and O.84.11.10 display lower churn and more stable performance, indicating greater resilience.

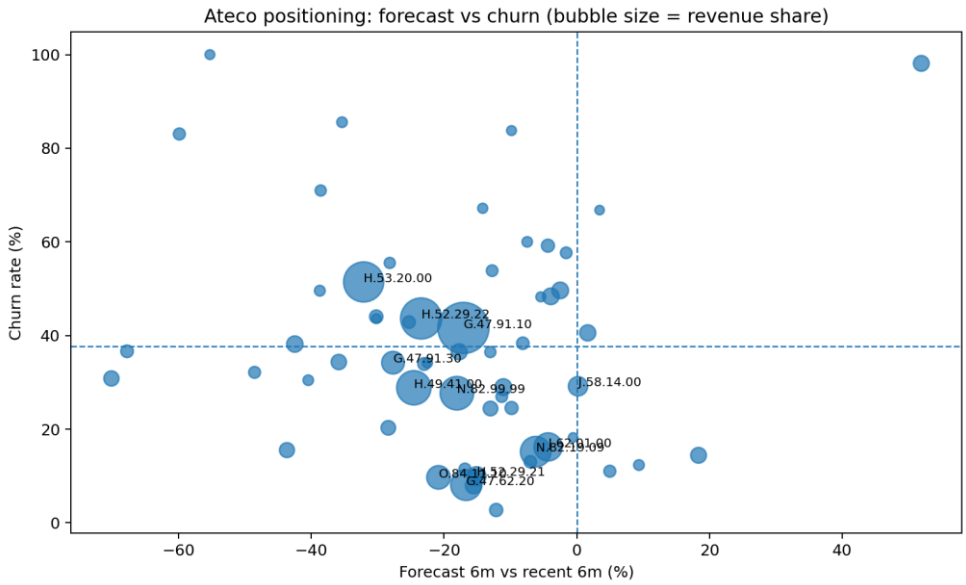

Figure 11 - ATECO codes by forecast change (horizontal axis) and churn rate (the vertical axis)

This analysis allows the company to distinguish between sectors requiring immediate retention and service intervention and those that should be defended and expanded as part of a long-term growth strategy.

4.2.5 Combined Analysis (Geography x Sector)

While individual geographic and sector analyses provide useful insights, they remain too broad to support precise decision-making. The combined geography × sector analysis enables the identification of specific market segments where revenue decline is concentrated, allowing the company to move from general diagnosis to targeted intervention.

The results confirm that underperformance is not uniform across regions or sectors, but rather concentrated in a limited number of region–sector combinations. Certain industries perform well overall but underperform in specific regions due to local competitive conditions, operational constraints, or demand characteristics. Conversely, weaker regions may still contain resilient sectors. This reinforces the need for a more granular analytical approach.

The first level of analysis examines macro-region × sector interactions. Table 5 highlights the most problematic combinations, where high revenue exposure overlaps with elevated churn, significant lost revenue, and negative forward outlook.

Macro-region	AtecoCode	AtecoDesc	Hist €m	Share %	Churn %	6m chg %	Lost €m	Fcst %
Northwest	H.49.41.00	Freight transport by road	6.58	2.0	16.5	-32.2	0.44	10.1
South	G.47.71.10	Clothing retail	0.52	0.2	13.9	-97.4	0.39	261.2
Northwest	G.47.91.10	E-commerce retail	8.10	2.4	56.0	-9.8	0.31	-4.3
Northwest	H.52.29.22	Freight transport	9.63	2.9	61.9	27.3	0.22	-32.8

Northwest	J.62.01.00	Software publishing (non-custom)	5.95	1.8	4.1	-7.4	0.18	1.4
Centre	G.47.91.10	E-commerce retail	7.75	2.3	23.0	18.1	0.14	-16.7
Northwest	M.70.22.09	Business consulting	1.57	0.5	10.2	-32.5	0.13	49.2
South	G.47.91.10	E-commerce retail	3.39	1.0	51.7	-9.4	0.13	0.9

Table 5 - Problematic Macro Regions x ATECO Codes

These combinations represent the company's most critical structural weaknesses, as both geographic exposure and sector dynamics reinforce each other. Priority should be assigned to combinations that combine scale, loss magnitude, and negative forecast, as they represent the highest economic risk.

At a more detailed level, territory × sector analysis provides the most actionable insights. Table 6 identifies the most problematic territory–sector combinations, showing that revenue decline is often driven by a small number of sector-specific issues within individual territories. Underperformance is often not uniform across an entire macro-region or an entire sector.

Territory	AtecoCode	AtecoDesc	Hist €m	Share %	Churn %	6m chg %	Lost €m	Fcst %
Milano	G.47.91.10	E-commerce retail	4.67	1.4	51.8	-13.0	0.21	5.7
Milano	H.52.29.22	Freight transport	5.59	1.7	78.4	45.2	0.16	-43.9
Roma	G.47.91.10	E-commerce retail	4.42	1.3	23.2	5.0	0.12	-2.4
Salerno	G.47.91.10	E-commerce retail	1.86	0.6	38.7	-21.6	0.09	12.5
Roma	O.84.11.10	Legislative and executive central/local government, financial administration	5.68	1.7	6.8	8.0	0.09	-30.9
Roma	N.82.99.99	Other business support service activities n.e.c.	0.51	0.2	17.0	-29.9	0.04	-10.5
Roma	G.47.71.10	Clothing retail	0.46	0.1	91.7	-36.0	0.03	39.9
Milano	N.82.99.99	Other business support service activities n.e.c..	1.73	0.5	84.9	-4.6	0.03	-3.4

Table 6 – Problematic Territories/Municipalities x ATECO Codes

This level of analysis reveals that many broad performance issues are in fact highly localized. A territory may appear to underperform overall, while the decline is concentrated in one or two dominant sectors. This allows the company to move from general geographic or sector-based strategies to precise, account-level intervention.

The concentration of revenue loss across geography–sector combinations is further illustrated in Figure 12, which shows that revenue leakage is driven by a small number of high-impact cells, particularly within the Northwest and Centre regions. For example, combinations such as Northwest × H.52.29.22 represent the largest pockets of loss, confirming that revenue decline is highly concentrated rather than diffuse.

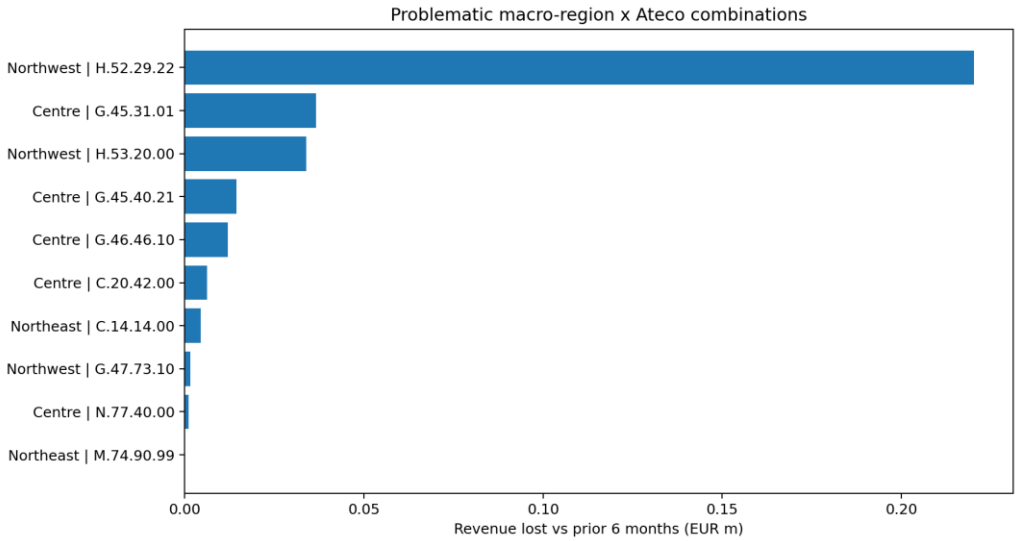

Figure 12 – Revenue Loss Concentration (Region × Sector)

Conversely, additional analysis (reported in Figure 19) identifies combinations with stable or positive performance. These represent areas where the company's commercial and operational model is better aligned with market conditions and can serve as reference points for growth and replication. The tables and figure provided in Annex B show breakdowns of: outperforming macro-region × sector combinations, territory × sector positive dynamics and revenue gain concentration

Overall, this combined analysis demonstrates that revenue decline is structured and localized, enabling the company to prioritize interventions where economic impact is greatest and to adopt a more targeted and efficient approach to performance management.

4.2.6 Strategic Insights

The results of this section give a clear understanding of the drivers of revenue decline and highlight the need for targeted intervention. First, revenue decline is primarily driven by fading customers, rather than fully inactive ones, indicating that revenue loss is a progressive process, which creates a window for proactive intervention before clients are lost completely.

Second, risk is not uniformly distributed, but concentrated in specific geographic regions, sectors and a combination of both. High-risk areas appear where high revenue exposure overlaps with elevated churn and negative forward outlook, distinctly in key regions such as the Northwest and in logistics-related sectors.

Third, it is inferred that revenue loss is highly localized, often concentrated in specific territory–sector combinations, which suggests that broad national or sector-wide strategies are insufficient, and that effective intervention must be targeted at the level of specific market segments.

Finally, the presence of a significant “Unknown” geographic category highlights a data quality limitation, reducing the precision of the analysis and the effectiveness of resource allocation. Overall, these findings indicate that revenue decline is structured, concentrated, and predictable, enabling the company to move from reactive analysis to targeted, data-driven intervention strategies.

4.3 Behavioural Segmentation and Strategic Targeting

Building on the insights delivered on Section 4.2, this section studies a behavioural segmentation of the client base aimed at supporting targeted strategic intervention.

4.3.1 Behavioural Segmentation Framework

Customers were classified into three operational activity states, grounded in their observed revenue dynamics across monthly shipment variables: Active, clients with stable or increasing logistics activity; Fading which are clients sowing declining activity and elevated churn risk; and Inactive which are client with no meaningful recent activity. This classification facilitates the identification of clients transitioning toward churn before they become inactive, turning churn analysis into a proactive process.

4.3.2 Alignment Between Behavioural Segments and Sector Structure

Behavioural patterns are not uniformly distributed but concentrated in specific sectors. Certain industries show a higher proportion of fading and inactive customers, indicating structural vulnerability associated with sector-specific dynamics (like demand variability or competition). The chart on Figure 13 describes the churn rate across different industries, calculated as the share of fading and inactive customer within each sector.

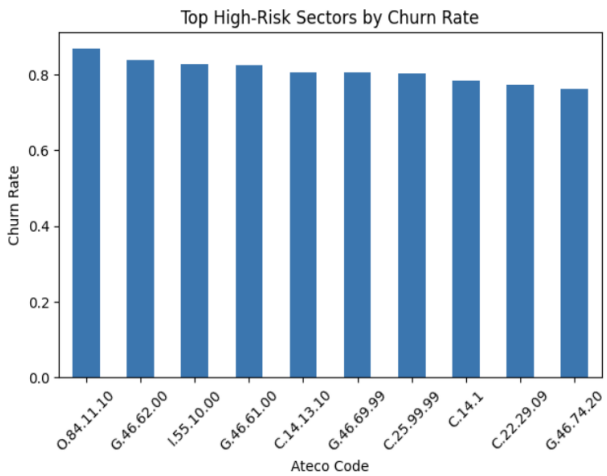

Figure 13 – Top High-Risk Sectors by Churn Rate

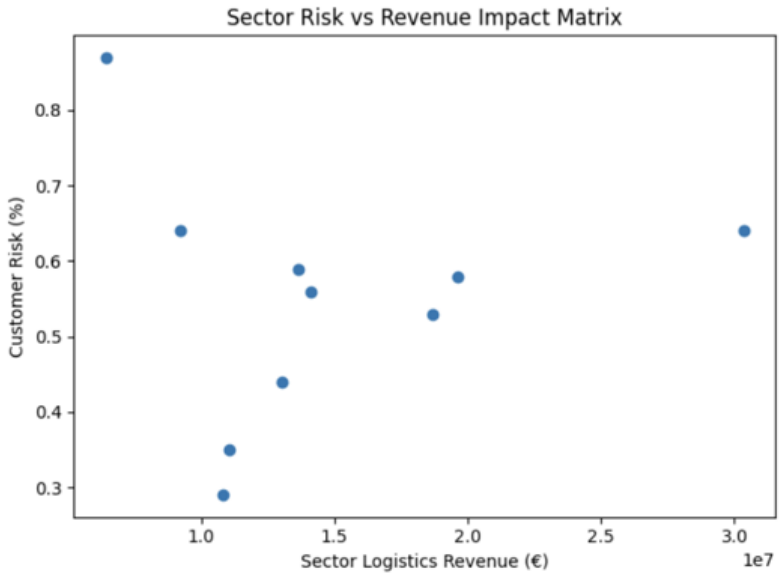
Sector-level revenue was combined with customer instability indicators to evaluate economic impact. It was concluded that risk is concentrated in sectors that combine high revenue contribution and high customer instability, turning them into the most critical areas for intervention. These findings reinforce earlier results, corroborating that sector composition is a key driver of revenue risk.



No	Ateco Code	Initial	Revenue (€)	Risk Share (%)
1	G.47.91.10	G	30339385	64.0
2	H.52.29.22	H	19608253	58.0
3	H.53.20.00	H	18699678	53.0
4	Altro / ND	A	14099285	56.0
5	H.49.41.00	H	13653389	59.0
6	N.82.99.99	N	13046869	44.0
7	G.47.62.20	G	11047631	35.0
8	N.82.19.09	N	10798028	29.0
9	J.62.01.00	J	9195565	64.0
10	O.84.11.10	O	6422786	87.0

Figure 14 – Sector Revenue vs Instability Matrix

4.3.3 Distribution and Revenue Exposure by Behavioural Segments

The distribution of clients across behavioural segments provides further insight into the structure of the customer base. As shown in Figure 15, the distribution of customers across behavioural segments shows that inactive clients represent the largest share of the base, while active customers account for a smaller but strategically important group.

Because fading customers remain active while showing early signs of decline, they represent the most relevant group for proactive intervention.

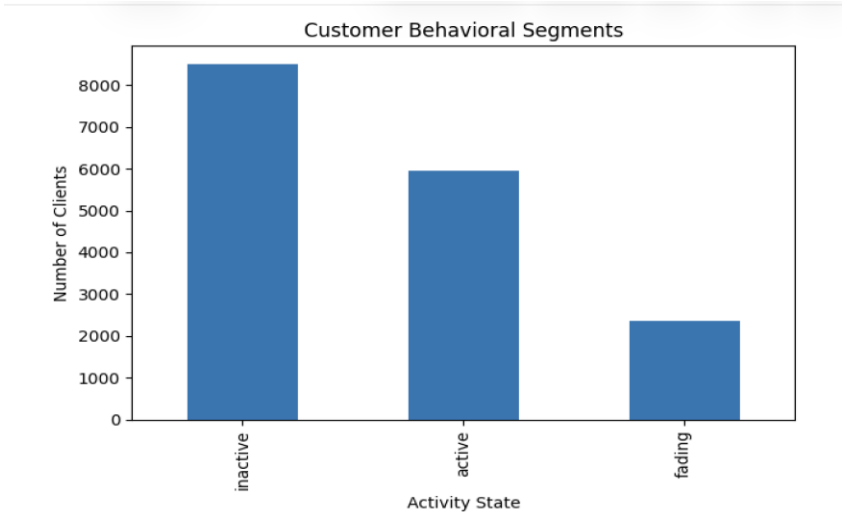


Figure 15 – Distribution of Behavioural Segments

To extend the analysis of customer distribution across behavioural segments, it was evaluated how revenue is allocated among these groups.

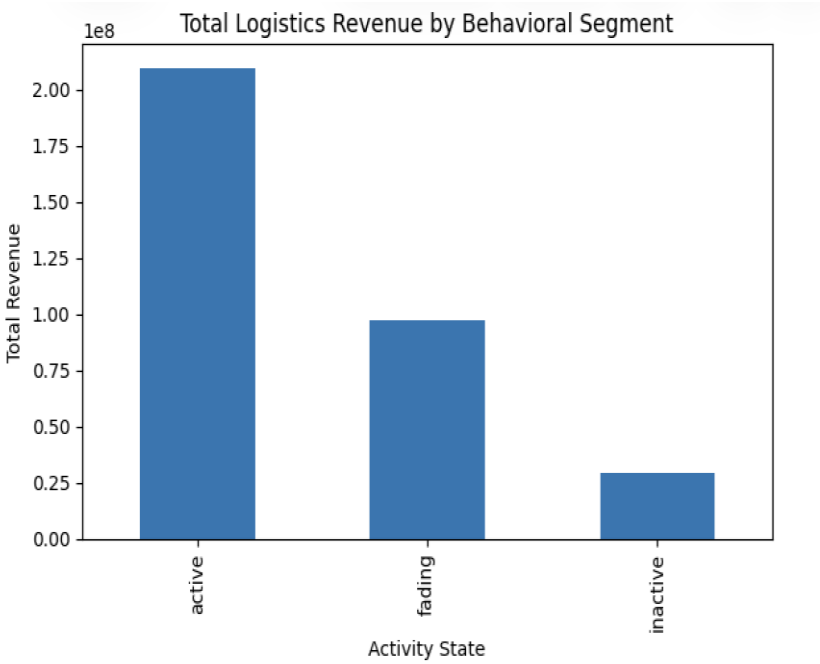

Figure 16 – Revenue Contribution by Behavioural Segment

While active customers generate the largest share of revenue, fading customers also contribute a significant portion, indicating that a substantial share of revenue is currently at risk but still recoverable. Revenue decline is primarily driven by customers in transition.

4.3.4 Strategic Targeting Framework

Considering the distribution of revenue across behavioural segments, the analysis moves from descriptive segmentation to strategic prioritization. Fading customers represent a relatively

smaller share of the total client base, yet they account for a disproportionately large share of revenue, turning them critical to business performance.

Practically, sectors and customer groups can be prioritized according to two dimensions: their economic importance and their level of instability, which leads to the following prioritization framework:

- High Priority Immediate Intervention): High revenue contribution and high proportion of customers. These segments represent the greatest risk to overall performance.
- Medium priority (Monitor and engage): Moderate revenue contribution with emerging instability. These segments require proactive monitoring and selective intervention;
- Low priority (Selective focus): Low revenue contribution, regardless of churn level. These segments have limited impact on total performance.

This ensures that resources are allocated efficiently, focusing on segments where intervention can generate the highest return. The results of Section 4.3 reinforce and extend the previous analyses: revenue is highly concentrated; decline is driven by fading customers and these risks are concentrated in specific sectors and behavioural segments.

4.4 Prescriptive Analytics and Action Plan

4.4.1 From Diagnosis to Prescriptive Decisions

The analysis in Sections 4.1, 4.2, and 4.3 provides a comprehensive understanding of revenue structure, customer dynamics, and risk exposure.

Section 4.1 reveals that revenue is highly concentrated across a limited number of customers, sectors, and geographic areas. Section 4.2 demonstrates that revenue decline is primarily driven by fading customers, which indicates a progressive and potentially reversible process. Section 4.3 further highlights that behavioural risk is concentrated in specific sectors and customer segments. Together, these findings confirm that revenue risk is concentrated and predictable, providing a strong foundation for targeted, data-driven intervention. This section translates these analytical findings into a structured and operational action plan. The focus is on identifying where intervention should occur, how resources should be allocated, and which actions are most likely to generate measurable impact.

4.4.2 Quantifying Revenue at Risk and Recovery Potential

Total historical revenue amounts to €336.76 million, of which 37.7% is associated with churn, including 28.9% at-risk (fading) and 8.8% inactive.

Recent performance shows €61.97 million in revenue over the last six months. However, €9.61 million has already been lost compared to the previous period, and the forecast indicates a decline to €48.73 million (-21.4%) in the next six months.

These results indicate that revenue decline is driven by progressive erosion within the existing client base, rather than sudden demand collapse. Importantly, a large share of this revenue remains recoverable, as it is linked to customers that are still active but declining. From a managerial perspective, this implies that the primary opportunity lies in intervening early to prevent further decline, rather than focusing exclusively on reactivating inactive customers.

4.4.3 Customer-Level Prioritization and Recovery Strategy

Given the high revenue concentration identified in Section 4.1, intervention must focus on high-value customers.

Priority should be given to customers combining high revenue contribution, recent decline, and negative outlook. In practical terms, this corresponds to approximately the top 100–200 declining accounts, which are likely to account for a disproportionate share of revenue loss.

Targeted actions should include account-level diagnostics, pricing adjustments, service improvements, and proactive engagement. Due to concentration effects, recovering a small number of high-value customers can generate significant impact.

4.4.4 Sector-Level Strategy and Portfolio Rebalancing

Sector-level analysis shows that risk is concentrated in a limited number of industries. For example, e-commerce (G.47.91.10) represents the largest exposure and loss (€1.13 million), while logistics-related sectors such as H.52.29.22 and H.53.20.00 combine high churn with negative forecasts.

These sectors require targeted retention strategies, including pricing flexibility, service adaptation, and increased engagement.

Conversely, more stable sectors should be prioritized for growth, supporting portfolio rebalancing. This dual approach allows the company to reduce risk while strengthening long-term performance.

4.4.5 Geographic and Territory-Level Intervention

Geographic analysis highlights significant regional disparities in performance. The Northwest region (31.9% of revenue) represents the largest exposure and loss (€3.01 million), while the Northeast and Centre exhibit the highest churn rates (43.8% and 40.7%, respectively).

At territory-level, key markets such as Milano and Roma combine high revenue with significant decline, making them priority areas for intervention. Other territories exhibit severe contractions, indicating localized demand shocks or operational issues. Territories should be managed through a three-tier approach: recover territories, which require immediate intervention, including detailed account reviews and targeted recovery campaigns; defend

territories, where focus should be on maintaining service quality and prevention of further erosion; and monitor territories that require observation but limited resource allocation.

4.4.6 Targeting High-Impact Geography-Sector Combinations

The most actionable insights emerge from combined geography–sector analysis (Section 4.2.5).

Revenue loss is concentrated in specific combinations, such as Northwest × H.52.29.22 and Northwest × H.53.20.00, which combine scale, high churn, and negative outlook.

These combinations should be prioritized through coordinated action between regional and sector teams, enabling more precise and effective intervention than broad strategies.

4.4.7 Forecast-Driven Decision Framework

The forecasted decline (-21.4%) indicates that recent performance improvements are unlikely to be sustained without intervention.

Forecast signals should be integrated into decision-making as early warning indicators. Segments with negative outlook should be prioritized for immediate action, while stable segments can be monitored.

This approach shifts the organization from reactive to prescriptive management.

4.4.8 Data Quality and Operational Monitoring

The presence of a large “Unknown” geographic category (20% of revenue) limits analytical precision.

Improving data quality should be treated as a priority, alongside the implementation of monitoring systems tracking customer activity, sector performance, and regional dynamics.

4.4.9 Strategic Synthesis and Expected Impact

The prescriptive framework developed in this section operates across three interconnected levels:

- Customer level: prioritize high-value declining accounts;
- Segment level: target high-risk sectors and geographic areas;
- Portfolio level: rebalance toward stable and growing segments.

By focusing on segments where revenue concentration and risk overlap, the company can maximize the impact of its interventions.

The expected outcome is a stabilization of revenue, a reduction in churn, and a more resilient and balanced portfolio over time.

5 Conclusion and Strategic Recommendations

5.1 Overall Findings

This study offers a comprehensive analysis of revenue dynamics, customer behaviour, and risk exposure within a logistics company using a data-driven approach.

The findings of this analysis indicate that revenue is highly concentrated, with 20% of customers generating 93.8% of total revenue. This is an indication of structural fragility, as performance depends on a limited number of high-value accounts.

The analysis further indicates that revenue decline is primarily due to a progressive deterioration among existing customers, rather than complete customer loss. A significant number of clients are classified as “fading,” indicating that revenue loss is gradual and potentially reversible.

Risk is also unevenly distributed, being concentrated in specific sectors, geographic regions, and customer segments. Logistics and e-commerce sectors, as well as regions such as the Northwest, combine high exposure with elevated churn.

Finally, forecast results indicate that recent performance improvements are unlikely to be sustained, highlighting the urgency of proactive intervention.

5.2 Key Insights

The findings of this study lead to several key strategic insights:

- Revenue risk with a limited number of customers, sectors, and regions driving both performance and vulnerability;
- Churn is progressive, with most revenue loss occurring through declining activity rather than abrupt exit;
- Performance is heterogeneous, requiring differentiated strategies across segments;
- Future performance is at risk, reinforcing the need for proactive, data-driven management.

5.3 Strategic Recommendations

Based on the analysis, a set of targeted strategic recommendations is proposed.

5.3.1 Prioritise High-Value Client Recovery

Focus on high-value customers showing early signs of decline.

Key actions include identifying the top 100–200 declining accounts, assigning senior account managers, conduct structured reviews to diagnose causes of decline and implementing targeted recovery measures such as pricing adjustments and service improvements.

5.3.2 Implement an Early-Warning System

Establish a system to detect early signs of customer deterioration by monitoring revenue changes and use forecast signals to trigger intervention on accounts that are flagged. This enables proactive intervention before full churn occurs.

5.3.3 Develop Sector-Specific Strategies

Differentiated strategies should be adopted across sectors.
For high-risk sectors, retention-focused actions are required (pricing flexibility, service adaptation), whereas stable sectors should be prioritized for growth and expansion.

5.3.4 Apply Geographic Targeting

Regional performance difference requires differentiated strategies. Segment regions should be classified into recover, defend, and monitor categories. For 'recover region's (high churn and high loss), reviews should be conducted at a territory-level and local sales and service presence should be strengthened. For 'defend regions', stable regions with high revenue, quality service should be prioritised and maintained, and unnecessary pricing pressure should be avoided. Performance should be tracked (but without heavy investment) for the 'monitor regions'.

5.3.5 Focus on High-Impact Geography x Sector Combinations

The most effective intervention occurs at the intersection of geography and sector. Prioritize intervention at the intersection of geography and sector, where revenue loss is most concentrated. Assign clear ownership and implement targeted recovery plans.

5.3.6 Improve Data Quality Monitoring

Resolve data limitations, mainly the "Unknown" geographic category and implement monitoring systems to track customer behaviour, sector performance and regional dynamics.

5.4 Managerial Implications

The results underscore the need for moving towards a data-driven management approach. Decision-making should focus on granular, segment-level insights rather than aggregated indicators, enabling more effective resource allocation, churn reduction and revenue stabilisation.

5.5 Limitations and Future Work

This analysis showed several limitations, such as reliance on historical data, incomplete information and a forecast with uncertainties. Future research should be complemented with external data, improve forecasting models and apply advance machine learning techniques to improve predictive accuracy.

5.6 Final Remarks

As previously said, revenue decline is a result of identifiable structural and behavioural patterns. Through a focus on high-impact customers, sectors, and regions, and a proactive and data-driven approach, the company can build resilience and sustain long-term performance.
